Acknowledgement

This survey has been carried out with the participation of many partners at different levels who are highly acknowledged. In particular, UNICEF for funding the survey, Concern Worldwide for implementing the survey, Ministry of Health for their direct participation, Feed the Children and Mercy USA for their active participation and their supervision roles they played during the survey. At the community level, special gratitude is due to the households which participated in the survey. The local administrators are also acknowledged for their role in mobilizing the community and acting as guides to the enumerators during the exercise. The survey teams composed of the enumerators and team leaders are highly appreciated for the hard work of collecting the high quality data to the best of the abilities. Special appreciations go to the DHMTs for Kajiado North, Kajiado Central and Loitokitok Districts and Nutrition Support Officer for Kajiado County. We also appreciate the dedication of the Data Entry Team throughout the process

Special gratitude goes to Kibet Chirchir of UNICEF/MoH for his active participation during the entire survey. Last but not least, appreciations are due to Yacob Yishak the Concern Country Nutrition Coordinator for his Technical Assistance throughout the process and the Concern Worldwide staff in Kajiado led by Regina Mbochi - Project Manager, Caroline Mugo – Assistant Project Manager, Weldon Ngetich – Nutrition Project Officer and Dan Otieno – Logistics Officer.

Executive Summary

The survey took place between 5th and 14th September 2012. Its general objective was to estimate the prevalence of malnutrition in children aged 6-59 months in Kajiado County, which constitutes Kajiado North, Kajiado central and Loitoktok districts. Specifically, the survey aimed at assessing the current prevalence of acute and chronic malnutrition in children aged 6 – 59 months, in addition to looking at Infant Young Child Nutrition (IYCN) practices, morbidity among under five children, Measles vaccination coverage and 'Vitamin A' supplementation, amongst other High Impact Nutrition Indicators (HINI). The survey also assessed the nutritional status of women of child bearing age, food security and food consumption patterns, water and sanitation situation as well as.

The survey was a cross sectional study with nutrition and food/ livelihood component according to SMART methodology and current best practices using 2 staged cluster sampling methodology. Focus group discussions and interviews with key informants were also done. The sample size was calculated using the estimated under 5 population size of 170,427 children (20% of the total projected¹ population for 2012) and the prevalence of malnutrition of previous survey in May 2011 (8.6%). 936 children (6-59 months), 244 children 0- 5 months and 699 households were included in this survey.

Using the new 2006 WHO standards, results show a prevalence of Global Acute Malnutrition (GAM), measured in weight for height Z-scores (WHZ), for children aged 6-59 months in this population as 4.7% (3.4 - 6.5%) for both genders and a prevalence of Severe Acute Malnutrition (SAM) of 0.6 % (0.2 - 1.6) with no statistical significant differences between the 2 genders for either severe or global malnutrition² although boys were slightly more moderately and severely malnourished than girls. The prevalence of SAM using Mid Upper Arm Circumference (MUAC) defined as less than 11.5 cm, was 0.8 % (0.4 - 1.5%). GAM using MUAC (< 12.5cm) was 3.1% (2.2 - 4.4%), with another 12% of children being at risk: MUAC 12.5 – 13.4 cm.

Younger children age group 6- 29 months were more moderately malnourished with MAM rate of 4.4 % for wasting compared to the older children 30- 59 months old whose MAM was 4%. On the other hand, the severe Acute Malnutrition rate of the latter was higher at 0.3% (1 child) with no younger children being severely malnourished. The 1 severe case was the same, presenting also with oedema giving a prevalence of odema at 0.3.

Given that this survey was done at a different season with the previous one done in May 2011, comparing the current GAM prevalence with the last one is not advisable. The prevalence of

¹ The Geometric Growth Model was used to project the population for 2012 based on the 2009 census data as the base population and the annual growth rate of 3.6 % as provided by KNBS

² P value is 0.699 and confidence intervals overlap and the difference likely due to chance. GAM for boys is 5.8 % (4.0 - 8.4 95% C.I.) and girls 3.7 % (2.1 - 6.4 95%) while SAM is 0.7 % (0.2 - 2.9 95% C.I.) and 0.5 % (0.1 - 1.9% respectively.

malnutrition among children under the age of 5 years was low and is classified as acceptable³ according to WHO classification.

The prevalence of stunting was however found to be high: 34.5 % (30.0 - 39.3 9%), with 11.3 % (8.6 - 14.6 95% C.I.) being severely stunted. Boys were more stunted than girls: 37.0 % (31.2 - 43.2 95%) and 32.1 % (27.0 - 37.7%) respectively for global stunting and with severe stunting prevalence of 12.3 % (8.8 - 17.0 %) for boys and 10.2 % (7.1 - 14.5%) for girls. It was also noted that the older children (30- 59 months) were more severely stunted at 13.4% compared to the younger 6- 29 months (9.4%). There was no significant difference in moderate stunting 23.5% for younger children and 23% for older children.

The proportion of chronic malnutrition in Kajiado is more than twice the national target of 16%⁴. In developing countries, the prevalence of stunting has been noted to start to rising at about three months of age and then slows at around two years of age. For children in the age group below two to three years, low height-for-age probably reflects a continuing process of failing to grow and for older children, it reflects a state of having failed to grow. Given that there is no significant difference in the age groups in Kajiado, this is an important fact when one is planning interventions to address stunting and further emphasizes the critical window of opportunity that exists for optimal nutrition from preconception to two years.

Other issues identified related to nutrition were:

1. 37.6% of the children sampled had been sick 2 weeks prior to the survey, most of them (19%) with ARI, followed by 7.9% fever, then 5.6% diarrhea. 24 cases (46.2%) of those diarrhoea cases was dysentery (have blood) and most of the diarrhoea (54.2%) were managed through use of ORS, 1.7% used Zinc, 11.9% used homemade solutions, 10.7% used septrin while another 6.8% used herbs. Only 34.9% of the children above 1 year were de-wormed have been de-wormed in the last 6 months- very low coverage only half of the households surveyed (52.8%) have mosquito nets, with most of them (89.9%) having received them from the MoH.
2. 87.2% of those children who had been sick sought some form of medical assistance: 47.3% went to public clinics/ dispensaries, 20.1% went to private clinics while 15% bought over the counter drugs. 1.6% used consulted local herbs for treatment.
3. Measles immunization amongst children 9 months and above is high at 85.5% with 57.3% being confirmed by the presence of vaccination card. Although no cases of measles were reported 2 weeks prior to the survey, key informant interviews and FGD discussions showed concern on suspected cases of measles particularly reported in North Kajiado. District statistics from the District health information system (DHIS) since January to September showed a total 441 suspected measles cases with Central reporting 108 of the cases; North: 253 and South: 80. Measles campaign was done in the North immediately the week after the survey, 15th- 19th,

³ WHO classifies prevalence of global acute malnutrition as <5% acceptable, 5- 9.9% as poor, 10- 14.9% as serious and >=15% as critical.

⁴UNICEF *et al.* Undated. Kenya HINI Leaflet: Nutrition strategies and programs in Kenya.

September with 59,811 children vaccinated,

4. The overall Vitamin A supplementation in the last 6 months 6- 59 months is low 46.9. 44% of children 12- 59 months received Vitamin A supplement, while among the 6- 11 months coverage was 64%. 24% of 12- 59 months received twice, while 72% received once. The coverage of Oral Polio Vaccine (OPV 1) and OPV 3 was 96.4% and 92.5% respectively while BCG coverage was 85.5%, although some villages especially in Kajiado North had poor vaccination coverage.
5. Infant young child feeding practices are still a main challenge in the county. 76.1% of children 0- 5 months initiated breastfeeding within the first one hour. However the exclusive breastfeeding rate still low (44.7%) although this is a significant improvement from 2011 when it was 14.7% (p value = 0.000). Practicing EBF among both HIV AIDs infected mothers and non-infected informed mothers remains a challenge. EBF however due to the fact that most mothers are bread winners and spend considerable time in the agricultural farming groups. Moreover, complimentary feeding after 6 months is also limited by the restricted diet that is locally available, which is mainly milk, maize meal, rice and occasionally beans. 303 out 390 children under 2 years (77.7%) were still breastfeeding although 46.4% of these were given other foods (including water) before they reached 6 months and 48.3% were given complementary feeding at 6 months.
6. 75.8% of the children 6- 23 that were still breastfeeding consumed 3 or more food groups, while the non-breastfed who ate 4 or more food groups were 69.8%. On meal frequency for the 6-23 months, 74.3% among those breastfeeding ate at least 3 meals, although of concern is the low percentage of the non-breastfeeding who ate at least 4 meals (42.3%). The percentage of households that usually eat 3 meals a day was 69.4% and this was very comparable to no. of households that had eaten the 3 meals the day prior to the survey (69.1%). Fewer people than usual ate more than 3 meals (3.4% against usual 7.1%) while slightly more people ate 1 or 2 meals than usual.
7. While the main source of food consumed is purchases 83.7% followed by own production at 11.9%, the main source of livelihood is livestock keeping (38.3%), followed by casual labour (14.4%) and farming (12.2%) and petty trade at 10.9%. The last general food distribution (done in early September) by Neighbourhood Initiative Assistance (NIA) consisted of 6kg of cereals, 1.2 kg pulses with 0.6 kg CSB, 0.4L of vegetable oil- all per person. Aid is distributed only at the climax of hunger season (July, Aug, Oct), only targeting rural areas in the county. 86,720 (21% of county population) are registered for food AID and 32.8% of sampled households received relief food at least once in the last 3 months (June- August 2012). although 33.5% reported that the food received lasted for less than one week, 31.2% reported that it had lasted for only one week
8. Maternal nutrition: The prevalence of malnutrition among 640 women was found to be 2.6%%, with 10.9% of mothers in Kajiado being at risk of being malnourished. 18.5% (MUAC < 21 cm and < 23 cm respectively. The pregnant and lactating women were slightly more malnourished (3.1%), with 12.8% at risk. Vitamin A supplementation amongst lactating women was low with at least 29.8% (n=22) of the sampled women receiving the supplement. 54% of all the women interviewed were given iron supplements in the last pregnancy, while 15.9%received folic acid. Most women interviewed (61.7%) gave birth at home with no assistance of skilled workers deliveries, although 3.1% were helped by a skilled attendant. Only 27.8% of the women delivered their last child in a health facility despite the fact that anemia has been noted to affect many child bearing women in the area. The high home deliveries have been attributed to several factors, including poor health care access with health facilities being up to 70 km away in

some areas, Poor infrastructure and lack of good communication networks worsens the health access as well as a highly patriarchal community in which the woman is not listened to as much & mothers in laws play a key role in determining child bearing and care practices.

9. On average the amount of water used daily per house hold is 58 Liters although this ranges from 10 Litre to 200 Litres. The average water used per person per day in Kajiado is 11 Litres. This is less than the minimum required as per sphere standards recommendation of 15 L per person per day⁵. Among the sources of water mentioned by the responded were water taps (33.5%), tanker (2.2%), unprotected wells (41.5%) while the rest were getting their water from lagas and earthen dams. Of the 64% of the households that does not have access to safe drinking water, 27.1% of them treat their water before drinking while 74.7% do not treat the water. The most common method of treating water among the households that practice water treatment was boiling (67.4%) 35.9% of households have access to safe water source while 45.5% have access to a toilet. Hand washing at critical times⁶ was found to be 23.6%

In conclusion the prevalence of acute malnutrition of children in Kajiado County has improved. Although the prevalence of wasting is low and at acceptable levels, concern is on the high prevalence of stunting levels, hence high chronic malnutrition. “Stunting in children below the age of five is a stronger indicator of hunger and one of its determinants, poverty, than other anthropometric indicators or estimates of per capita income. This is because stunting indicates the chronic restriction of a child’s potential growth, reflecting the cumulative effects of inadequate food intake and poor health conditions that result from endemic poverty’ (United Nations Standing Committee 2010)⁷. In order to successfully and sustainable address stunting, it is critical that an integrated approach is applied.

HINI components are still low especially Vitamin A coverage (and in particular among the 12- 59 months who took the supplements twice in the last 1 year); Zinc supplementation in managing diarrhoea is low. De-worming coverage is also low as well as exclusive breastfeeding rates. Although the overall county immunization coverage for measles, OPV and BCG are excellent, some pockets of concern have very poor coverage, especially in Kajiado North. There is still stigmatization of HIV/AIDS: It is taboo to discuss the subject openly.

Short term/ mid term

- Frequent measles vaccination campaigns especially in areas where access to health facilities is a main challenge, with timely interventions when suspected cases are highlighted.
- Mothers of infants and young children require much health and nutrition education, as the available research shows that effects on linear growth seem to be best with interventions that also provide specific educational messages such as importance diet diversity and emphasize of

⁵ Sphere Handbook. **The Sphere Project**- Humanitarian Charter and Minimum Standards in Disaster Response

⁶ Hand Washing at critical times includes washing hands after visiting toilet, before handling food, after cleaning Childs bottom, before feeding the child and before eating

⁷ Jane Badham, Lara Sweet. 2010; Stunting: An Overview. SIGHT AND LIFE Magazine

the critical window of opportunity that exists for optimal nutrition from preconception to two years.

- Scaling up HINI indicators is essentially (especially Vitamin A supplementation, de-worming and using Zinc for diarrhoea management) as well as iron supplementation for PLWs through strengthening of outreach services to supplement long distance/ access to health facilities.
- Roll out of micronutrient supplementation program in districts that have not yet started (e.g. central) with refresher training for health facility staffs especially in Kajiado central on enhanced management of diarrhoea in order to promote Zinc usage.
- District based surveillance systems could be established to help individual districts monitor the HINI indicators at relatively lower costs.
- Implementation of the community strategy which also addresses challenges of access to the health facilities should be supported by MoH and its partners in the various districts.
- Specific pocket areas where the GAM/ SAM might be of concern e.g. flower farms, slums etc can be addressed by continuous surveillance and if need be appropriate targeted interventions done in those areas.
- Streamline and adherence to the admission criteria to targeted nutrition program among all partners working in IMAM.
- Partners should invest in more Livelihood intervention programs and scale up interventions such as adopting livelihood diversifications to have a shift from over-dependence on pastoralist & adopt income generating activities e.g. small scale trade, more market participation e.g. selling livestock products, bee keeping & honey production.
- It is necessary to have health education sessions on HIV targeting all community members (both infected and non infected/ affected at the community level to help reduce stigma and also to address information gap on IYCN in the context of HIV.
- DHMT Central and the district hospital should look into the concerns raised about the district hospital and work at restoring community confidence on service delivery.

Long term

1. MoH & Partners need to invest in address the Health care access challenges (distance, attitude) by constructing more health facilities and the need to continually encourage hospital deliveries.
2. Cultural reasons for home deliveries should be addressed through continuous health education while exercising best practices in behaviour change communication.
3. Scale up WASH program to cover all areas of the county in both urban, semi urban and the rural areas

Proportion of Households with ITNs	676	354	52.3%

CHAPTER 1

BACKGROUND

1.1 Introduction

Kajiado County is located in the Rift Valley and comprises of three districts; Kajiado North, Kajiado Central and Loitoktok Districts. It covers a total area of 21,900.9 Square kilometers, with an estimated population of 687,312 out of which 137,466 are children under five years old, according to the 2009 Census. There are five different livelihoods namely; Pastoral, Agro pastoral, Pastoral/Leasing, Mixed farming and Formal employment/Casual waged labor/Business. The landscape consists of plains and some volcanic hills and valleys. The region is very dry with only seasonal rivers and is officially designated as a semi-arid region.

The annual rainfall ranges between 500-1250mm and is poorly distributed in amounts and spread. In recent years there have been long periods of drought when there has been little or no rains to support a predominantly pastoralist population. The indigenous people of the area are Maasai but there is an increasing influx of people from other tribal groups contributing to increased pressure on the land and other resources, including water.

Although generally the long rains in 2012 were above normal in most of the areas in the county, the southern parts of the county where the Loitoktok District falls experienced failed rains for 2 consecutive seasons and the impact was especially felt as the short rains are mostly depended on in the Southern parts for farming. Loitoktok district is already being faced with human wildlife conflict owing to the competition of available pasture and water for the livestock and wild animals. Despite adequate pasture that is likely to last for the next two months, in most of the county, the amount of water available is minimal and is drastically reducing and is likely to result in livestock migration to the neighboring districts, which may result in increased prevalence of livestock diseases as well as reduced milk availability at household level. This may negatively affect the nutrition status of children.

Overall the food and nutrition security situation has improved compared to last year, based on the data and information collated during the August 2012 Long Rains Assessment, as a result of : good long rains performance, improved water availability and trekking distances for both human and livestock (4-6KM⁸), good animal body conditions, however, the milk availability at household level was found to be low, owing to the low household stocks of livestock stemming from the trailing effects of the 2009 and subsequent droughts. The nutrition situation according the MUAC data for children less than 5 years of age had improved slightly from 10.8% to 9.8% (MUAC less than 135MM)⁹. This improvement in the food security situation resulted in recommendation by the Kenya Food Security Steering Group for a slight reduction in the number of beneficiaries under the Protracted Relief and Recovery Operations.

However, aggravating factors that are likely to alter the current nutrition and food security situation include the poor rains in the Southern region (the main source of food for the County) that are likely to

⁸ Kajiado District Early Warning System Bulletin-July 2012

⁹ Arid Lands

result in a deterioration of food security in the agro pastoral areas in the South where below average rainfall in most of the rain-fed farming areas were received in the last 2 season, suggesting an inevitable shortfall of harvest, while in some locations, total crop failure was experienced. The prevailing unfair terms of trade in some areas 2012 is yet another factor, with current cereal-meat ratio being unfavorable due to scarcity and souring food prices., for instance, a 90kg bag of maize costs between sh 3000 and 4000 while a Goat sells for between sh 4,000 and 4,500. In addition, pulses and cereals prices are still high with most of them being sourced from Namanga and neighboring districts of Tanzania. Livestock diseases for instance the Contagious Caprine Pleuro Pneumonia (CCPP) that was reported in most pastoral areas in the month of July are also likely to affect livestock production.

The prevalence of human diseases which have direct impact on the nutrition status of children less than 5 years is also high, with secondary data indicating diarrhea and Acute Respiratory infections being prevalent¹⁰. The chronic long-term challenges such as poor child feeding and care practices among the pastoralist community as was evidenced in the KAP survey conducted in early 2012¹¹ are also likely to negatively impact on the nutrition status of children under 5 years. For instance Exclusive Breastfeeding rates and timely introduction of solid and semi-solid foods stood at 33.9% and 27.5% respectively, both of which are suboptimal and way below the national recommendations, notwithstanding the nutrition and health and nutrition education that was undertaken by Concern and its partner (NIA) since 2009 in the Kajiado Central and Loitokitok Districts. This is in addition to the poor dietary diversity (25.3%) and low rates of continued breastfeeding at 1 year (43.2%),are all factors that negatively affect the nutrition status.

1.2 Rationale of the Survey

In order to assess the levels of malnutrition and the performance of the HiNi indicators in the greater Kajiado District, Concern Worldwide in collaboration with MoPHS and UNICEF carried out a nutrition survey. This survey was conducted between 5th September and 14th September 2012 and helped in evaluating the extent of malnutrition among the children aged 6-59 months and recommended appropriate interventions

1.3 Objectives

1.3.1 Overall Objective

The general objective of the survey was to estimate the prevalence of malnutrition in children aged 6-59 months in the Kajiado County.

¹⁰ Preliminary findings of the Kajiado County Long Rains Assessment-August 2012

¹¹ Concern Worldwide Kajiado and Oloitokitok KAP survey 2012

1.3.2 Specific Objectives:

- To estimate the current prevalence of acute malnutrition in children aged 6 – 59 months
- To estimate Measles, de-worming, BCG vaccination and 'Vitamin A' supplementation coverage for children 9-59 months and 6-59 months respectively
- To assess the current food security situation of the surveyed population
- To measure the Wash indicators
- To measure the Morbidity rates of children 6-59 months 2 weeks prior to the survey
- To measure the IYCN indicators

1.4 Timing of the Survey

The survey was undertaken between 5th September and 14th September, 2012. Training, including standardization test and piloting of the data collection tools were conducted from 5th and 8th September, 2012 and thereafter data collection from 9th to 14th September, 2012. Data entry was done in the evening following data collection

1.5 Seasonal Calendar

Figure 1: Seasonal calendar for Greater Kajiado District

1.6 Area Surveyed

The survey was conducted in Kajiado County which comprises of three districts namely; Kajiado North, Kajiado Central and Loitokitok Districts and covered all the eight divisions namely; Central, Ngong, Magadi, Mashuru, Loitokitok, Ewaso Kedong, Isinya and Namanga. Kajiado County is found in the Southern part of the Rift Valley Province bordering Tanzania. Located in the Arid and Semi-Arid Lands (ASALs), pastoralism dominates the area with some agro-pastoralist areas in Kajiado and some distinct agrarian areas in Loitokitok; agricultural produce from these areas in Loitokitok also supplies markets in Kajiado District. The area is predominantly inhabited by the Maasai but changes in the traditional land tenure system (shift from communal to individual and increase in privatization) are causing them to consider selling the land. This implies a threat to the traditional communal grazing arrangements that enabled livestock to be moved around flexibly to good grazing areas.

Figure 2: Map of the Larger Moyale District

1.7 Methodology

1.7.1 Study Design

The survey applied a two stage cluster sampling using the SMART methodology with the clusters being selected using the probability proportional to population size (PPS).

1.7.2 Study Population

The target population for this survey was the children aged 6 – 59 months for the anthropometric component, 0 – 5 for the EBF rates and the caregivers of the targeted children.

1.7.3 Sample Size

The sample size was calculated using the SMART survey calculator. The projected village population sizes for 2012 for the county were used as the sampling frame. The population was projected using the Geometric Population Growth Models with the annual growth rate being 3.6%¹².

1.7.4 Sample Size Calculation for the Anthropometric/Malnutrition

The malnutrition/anthropometric sample size was based on the following parameters:

1. Malnutrition prevalence: The estimated prevalence of malnutrition of 8.6¹³ was used based on the 2011 survey
2. The design effect: taking in to consideration the heterogeneity of the survey area and the results of last year survey a design effect of 2 was used
3. The precision: As the estimated malnutrition prevalence was 8.6%, a precision of 3% was required to obtain an accurate estimate of malnutrition prevalence.
4. Under 5 populations: The total under 60 month's population of the survey area was **170,427** (20% of the total projected¹⁴ population for 2012)
5. The May 2011 nutrition survey identified 1.4 under-five population per household.

Table 2: Anthropometry sample size for Kajiado County

Population	U5 Pop.	Estimated Prevalence	Precision	Design Effect	% of Non-Response	Sample Size	HH to be Included	# Cluster
764,246	170,427	8.6%	3%	2	3%	730	658	36

Based on the above information, every cluster had 19 households which were sampled and expected to produce at least 21 children between 6 and 59 months.

All accessible villages were included in the initial sample selection with each village considered a cluster and clusters sampled with probability proportional to size. In addition, all the villages within Kitengela, Ngong, Rongai and Kiserian Townships were excluded from the sampling frame in order to eliminate the

¹² Growth Rate as Projected by the Kenya National Bureau of Statistics
13 May 2011 survey result

¹⁴ The Geometric Growth Model was used to project the population for 2012 based on the 2009 census data as the base population and the annual growth rate of 3.6 % as provided by KNBS

bias of areas surrounding Nairobi as well as factoring in the element of most partners in the greater Kajiado work in divisions further from Nairobi and the high population density in Ngong township (52.6% of all county population lives in urban Ngong).

All villages along with their respective populations were entered into the ENA software and clusters selected accordingly using the SMART ENA software. At stage two each team used the modified EPI method in household selection. Within the selected households all children 6-59 months were measured.

1.7.6 Sample Size Calculation for the IYCF

For the IYCF sample size, it was decided that the sample be calculated separately for the EBF targeting under 6 months children and the other components of IYCF. The EBF rate was used for the calculation of the EBF sample size. The following were the parameters which were considered for the sample size:

1. The EBF rate – 15%
2. Precision – 5%
3. Design Effect – 2

Based on the above parameters, the sample size for the under-6 months (0-5) children was found to be 243 children. The 243 children were distributed equally among all the 36 clusters such that every cluster needed to produce 7 children. Further, the 7 children from every cluster were selected from the households where the anthropometric survey was done. However, in case the 7 children were not found from the selected households, they were then selected purposively.

Table 3: IYCF Sample Size

Indicator	Estimated Prevalence	Design Effect	Sample Size
Timely initiation of breastfeeding (children 0-23 months)	59%	2	311
Exclusive breastfeeding under 6 months	15%	2	243
Timely complementary feeding	50%	2	341
Continued breastfeeding	50%	2	341

1.7.7 Cluster Selection

All accessible villages were included in the initial sample selection with each village considered a cluster and clusters sampled with probability proportional to size. All villages along with their respective populations were entered into the ENA software and clusters selected accordingly. At stage two household were selected using the modified EPI method. Within the selected households all children 6-59 months were measured.

1.7.8 Data Collected and Data Collection Methods and Tools

Both qualitative and quantitative data collection methods were used to collect the survey data; the following data were collected:

1. Anthropometry (weight, height, edema, MUAC, age, sex) for children and MUAC for mothers

2. Vaccination information (measles, BCG, and Vitamin A supplementation)
3. Incidences of childhood illnesses in the last 2 weeks prior to the survey
4. Other child care, food security and hygiene data at household level
5. IYCN data

1.8 Organization of the Survey

- **Coordination/Collaboration:** before the survey was conducted meetings were held with the respective district authorities and key stakeholders to brief them about the purpose, objectives and methods for the survey. The survey details were discussed with the District Health Management Team, key partners on the ground (NGOs and UN) and conducted in collaboration with the District Health Office. The authorities were requested to officially inform the communities (villages) that will be involved in the assessment.
- **Recruiting the Survey Team:** recruitment was done in collaboration with the District Health Office to give ownership and participation in the assessment. Six teams of four were selected to include two measurers, one enumerator and a team leader.
- **Training of the Survey Team:** The teams were given 4-day training prior to field work, including a standardization test to ensure standardization of measurement and recording practice. All data collectors were trained on taking anthropometric measurements, completion of questionnaires and sampling methodology. The data collection forms and questionnaires were pilot tested in clusters not selected to be part of the larger survey, to ensure that the interviewers and respondents understand the questions and that interviewers follow correct protocols
- **Team work in the field:** Six teams each with four members who had been trained were formed consisting of 1 team leader, interviewer and 2 measurers. In addition, supervisors from Concern, MoH, and other partners (UNICEF Feed the Children and Mercy USA) were closely supervising the team throughout the survey. In moving from one randomly selected household to another, the teams were guided by a village leader, or a community volunteer, depending on the village and who was available.

1.9 Data Entry, Analysis and Report Writing

- **Data Analysis:** the data entry and analysis was done using ENA for SMART, CPro and SPSS Statistical softwares. In addition, to improve on the data entry quality, there was double data entry.
- **Preliminary Results and Final Report:** the preliminary findings were submitted by the consultant to the DHMT, stakeholders and Concern within two weeks of completion of the survey fieldwork at District and National level and included the prevalence of global acute malnutrition as well as the prevalence of moderate and severe acute malnutrition, vaccination and other relevant information. This final report was also submitted within one month of data collection and includes a description of methods used, to demonstrate appropriateness of sampling, data collection and data analysis. The report uses existing secondary data to support the findings of the assessment.

CHAPTER 2 RESULTS AND DISCUSSION

2.1 Household Demographic Characteristics

The total number of households that participated in the survey was 699 from which 936 children aged 6 to 59 months were measured. The total number children aged 0 – 23 months from the survey was 556 while there were 244 children surveyed for the EBF practices. The average number of persons per household in Kajiado County was 5.6 (S.D=2.3) which is almost the same with the average household size of 5.7 (S.D=2.1) found in the 2011 survey¹⁵. This implies that the composition of the household in Kajiado County has remained the same. In addition the number of children aged 0 – 5 months per household being 0.12 (S.D=0.3) while the average number of children aged 6 – 59 months per household was 1.3 (S.D=0.6). The proportion of under 0 -5 years old from the sampled households was found to be 28.8% (27.7 – 29.8, 95% C.I).

Table 4: Demographic Characteristics

DEMOGRAPHY	Number	
Number of HH surveyed	699	
Number of children 6-59 months surveyed	936	
Number of children 0-23 months surveyed for IYCN	556	
Number of children 0-5 months surveyed for EBF	244	
Average number of persons per HH	5.6	S.D = 2.3
Average number of children (0-5 months) per HH	0.12	S.D=0.3
Average number of children (6-59 months) per HH	1.3	S.D = 0.6

2.2 Distribution of Sample by Sex and Age

According to the results of the survey, 50.9% of the sampled children aged between 6 and 59 months were boys while the 49.1% were girls (Table 4). Irrespective of the fact that there were more boys than girls in the sample, the overall sex ratio was 1.0 demonstrating un-biased sample since the recommended range of the sex ration is 0.8-1.2¹⁶. The results also show that the age group 42- 53 particularly the boys were under-represented in the sample which was attributed mainly to absenteeism of the boy child who mostly had accompanied their fathers in the herding as reviewed during key informant interview, in addition to the fact that several older children, (4 and 5 year olds), were also away in schools. These factors could also have attributed to the over representation of the younger 6 - 17 months. The results of the age – sex distribution are presented below:

¹⁵ Kajiado SMART Survey, 2011

¹⁶ Assessment and Treatment of Malnutrition in Emergency Situations, Claudine Prudhon, Action Contre La Faim (Action Against Hunger), 2002.

Table 5: Distribution of Age and Sex of Sample

AGE (mo)	Boys		Girls		Total		Ratio
	no.	%	no.	%	no.	%	Boy: Girl
6-17	133	50.2	132	49.8	265	29.3	1.0
18-29	121	54.3	102	45.7	223	24.7	1.2
30-41	98	51.6	92	48.4	190	21.0	1.1
42-53	80	50.0	80	50.0	160	17.7	1.0
54-59	28	43.1	37	56.9	65	7.2	0.8
Total	460	50.9	443	49.1	903	100.0	1.0

2.3 Nutrition Status of Children 6 – 59 Months

2.3.1 Wasting

Table 6: Prevalence of Acute Malnutrition Based on Weight-for-Height Z-Scores (and/or Oedema) and by Sex

	All n = 885	Boys n = 448	Girls n = 437
Prevalence of Global Malnutrition (<-2 z-score and/or edema)	(42) 4.7 % (3.4 - 6.5 95% C.I.)	(26) 5.8 % (4.0 - 8.4 95% C.I.)	(16) 3.7 % (2.1 - 6.4 95% C.I.)
Prevalence of moderate malnutrition (<-2 z-score and >=-3 z-score, no oedema)	(37) 4.2 % (3.1 - 5.7 95% C.I.)	(23) 5.1 % (3.6 - 7.2 95% C.I.)	(14) 3.2 % (1.7 - 5.8 95% C.I.)
Prevalence of severe malnutrition (<-3 z-score and/or oedema)	(5) 0.6 % (0.2 - 1.6 95% C.I.)	(3) 0.7 % (0.2 - 2.9 95% C.I.)	(2) 0.5 % (0.1 - 1.9 95% C.I.)

The prevalence of oedema is 0.3 %

The above table presents the prevalence of acute malnutrition based on Weight-for-Height Z-scores (and/or oedema). The results indicate a Global Acute Malnutrition (GAM) rate of all children as 4.7% (3.4 – 6.5 95% C.I.) which is acceptable¹⁷ based on the WHO standards. The prevalence of Severe Acute Malnutrition (SAM) for all children was established to be 0.6% (0.2 – 1.6 95% C.I.) which implies that the SAM prevalence fell short of the emergency levels¹⁸. Further analysis of the GAM rates by gender showed that the prevalence of GAM among the boys [5.8% (4.0-8.4 95% C.I.)] was higher than among the girls' [3.7% (2.1-6.4 95% C.I.)]. However the difference was statistically insignificant as the confidence intervals were overlapping. In addition, the prevalence of SAM was found to be high in boys [0.7% (0.2-2.9 95% C.I.)] than in girls [0.5% (0.1-1.9 95% C.I.)] though the difference was insignificant (p=0.699).

¹⁷ WHO cut off points for wasting using Z score (-2 Z scores in populations: <5%; 5-9% poor; 10-14% serious; >15% critical)

¹⁸ Emergency Level SAM >4%

Figure 3: Distribution of Weight-for-Height Z Scores for the Sampled Children

Figure 3 above compares the nutrition distribution curve of the sampled population with the WHO curve. The mean of the nutrition distribution of the sampled population was established to be -0.24 with a standard deviation of 1.07 which indicates a shift to the left of the sample curve when compared with the standard population curve implying a poorer nutrition status compared with the WHO reference population.

Table 7: Distribution of acute malnutrition and oedema based on weight-for-height z-scores

	<-3 z-score	>=-3 z-score
Oedema present	Marasmic kwashiorkor No. 0 (0.0 %)	Kwashiorkor No. 3 (0.3 %)
Oedema absent	Marasmic No. 11 (1.2 %)	Not severely malnourished No. 891 (98.5 %)

According to the above table, 11 children (1.2%) were marasmic (severely wasted) while 3 children (0.3%) had oedema, hence had kwashiorkor.

Table 8: Prevalence of Acute Malnutrition by Age, based on Weight-for-Height Z-Scores and/or Oedema

Age (mo)	N	Severe wasting (<-3 z-score)		Moderate wasting (>= -3 and <-2 z-score)		Normal (>= -2 z score)		Oedema	
		n	%	n	%	n	%	n	%
6-17	254	0	0.0	9	3.5	243	95.7	2	0.8
18-29	221	0	0.0	12	5.4	209	94.6	0	0.0
30-41	181	0	0.0	6	3.3	174	96.1	1	0.6
42-53	152	1	0.7	6	3.9	145	95.4	0	0.0
54-59	65	0	0.0	4	6.2	61	93.8	0	0.0
Total	873	1	0.1	37	4.2	832	95.3	3	0.3

Further analyses were done on the prevalence of GAM rates by age groups. The children aged 54 to 59 months were found to be more malnourished (6.2%) compared to any other age group. In addition, the age group 30 to 41 was found to be the least malnourished (3.3%) compared with the other age groups. However, there was significant difference between the prevalence of GAM in the two groups ($p=0.376$) i.e. those aged between 54-59 and those aged 30-41, these were the groups with the highest GAM prevalence and least GAM prevalence respectively.

Table 9: Prevalence of acute malnutrition based on the percentage of the median and/or oedema

	n = 905
Prevalence of global acute malnutrition (<80% and/or oedema)	(20) 2.2 % (1.4 - 3.5 95% C.I.)
Prevalence of moderate acute malnutrition (<80% and >= 70%, no oedema)	(15) 1.7 % (1.0 - 2.9 95% C.I.)
Prevalence of severe acute malnutrition (<70% and/or oedema)	(5) 0.6 % (0.2 - 1.6 95% C.I.)

The above table presents the results of the prevalence of acute malnutrition based on the percentage of the median and/or oedema. The weight-for-height percentage of the median (WHM) is a less sensitive indicator of acute malnutrition compared to the Z score. As expected the prevalence of GAM and SAM by WHM were 2.2 % (1.4 - 3.5 95% C.I.) and 0.6 % (0.2 - 1.6 95% C.I.) respectively which were lower than the GAM and SAM using the Z score.

Table 10: Distribution of MUAC by Nutrition Status

Indicator	Criteria	n	%
Severe Acute Malnutrition based on MUAC < 11.5 cm and/or Oedema	<11.5 cm	7	0.7
Moderate Acute Malnutrition based on MUAC 11.5 – 12.4 cm	>= 11.5 - <12.5 cm	22	2.4
At Risk based on MUAC 12.5 – 13.4 cm	>=12.5 - <13.5 cm	112	12.0
Normal	>=13.5 cm	782	84.9

MUAC is the commonly used indicator for admission in nutrition programmes in Kenya (both Supplementary Feeding Programme (SFP) and Out Patient Therapeutic Programme (OTP)). According to

the MUAC index, the prevalence of GAM was 3.1% and SAM was 0.7% while 12.0% of the children were at risk of malnutrition.

2.3.2 Underweight - Weight-for-Age (WFA)

The measure of underweight gives a mixed reflection of both the current and past nutritional experience by a population and is very useful in growth monitoring. Children whose WFA Z scores fell below -2 standard deviations of the WHO reference population or had bilateral oedema were classified as underweight. Children whose WFA Z score fell below -3 standard deviation of the WHO reference population or had bilateral oedema were classified as severe underweight. The table below presents the prevalence of underweight in Kajiado County.

Table 11: Prevalence of Underweight Based on Weight-for-Age Z-Scores by Sex

	All n = 873	Boys n = 441	Girls n = 432
Prevalence of Underweight (<-2 z-score)	(145) 16.6 % (13.2 - 20.7 95% C.I.)	(77) 17.5 % (13.8 - 21.9 95% C.I.)	(68) 15.7 % (11.8 - 20.7 95% C.I.)
Prevalence of Moderate Underweight (<-2 z-score and >=-3 z-score)	(120) 13.7 % (10.7 - 17.5 95% C.I.)	(65) 14.7 % (11.2 - 19.2 95% C.I.)	(55) 12.7 % (9.5 - 16.9 95% C.I.)
Prevalence of Severe Underweight (<-3 z-score)	(25) 2.9 % (1.8 - 4.5 95% C.I.)	(12) 2.7 % (1.6 - 4.5 95% C.I.)	(13) 3.0 % (1.6 - 5.5 95% C.I.)

According to the above table, 16.6% (13.2 – 20.7 95% C.I) of all the children were underweight which according to the WHO classification was considered medium¹⁹. The prevalence of underweight was high among the boy 17.5% (13.8 – 21.9 95% C.I) than in girls 15.7% (11.8 – 20.7 95% C.I). However the difference in the prevalence of underweight among the genders was insignificant as the confidence intervals were overlapping. In addition, the results showed that the prevalence of severe underweight was 2.9% (1.8 – 4.5 95% C.I) with girls being more severely underweight 3.0% (1.6-55 95% C.I) more than the boys 2.7% (1.6 – 4.5 95% C.I) though the difference among the gender was insignificant (p=0.709).

¹⁹ WHO guide lines for wasting: <10% - low, 10% – 19% - Medium, 20% – 29% - High, and > 30% Alarming/Critical

2.3.2 Stunting – Height-for-Age (HFA)

Stunting (height for age) is an indicator of chronic (long-term) malnutrition arising from persistently poor food security situation, micronutrient deficiencies, recurrent illnesses and other factors which interrupt normal growth. Unlike wasting, stunting is not affected by seasonality but rather related to the long-term effects of socio-economic development and long-standing food insecurity situation. Table 11 presents the prevalence of stunting desegregated by gender

Table 12: Prevalence of Stunting Based on Height-for-Age Z-Scores and by Sex

	All n = 843	Boys n = 422	Girls n = 421
Prevalence of Stunting (<-2 z-score)	(291) 34.5 % (30.0 - 39.3 95% C.I.)	(156) 37.0 % (31.2 - 43.2 95% C.I.)	(135) 32.1 % (27.0 - 37.7 95% C.I.)
Prevalence of Moderate Stunting (<-2 z-score and >=-3 z-score)	(196) 23.3 % (20.0 - 26.9 95% C.I.)	(104) 24.6 % (20.1 - 29.9 95% C.I.)	(92) 21.9 % (17.5 - 26.9 95% C.I.)
Prevalence of Severe Stunting (<-3 z-score)	(95) 11.3 % (8.6 - 14.6 95% C.I.)	(52) 12.3 % (8.8 - 17.0 95% C.I.)	(43) 10.2 % (7.1 - 14.5 95% C.I.)

The prevalence of stunting was found to be 34.5% (30.0-39.3 95% C.I) which according to the WHO classification of stunting was high²⁰. Further analyses showed that the prevalence of stunting among the boys 37.0% (31.2-43.2 95% C.I) than in girls 32.1% (27.0-37.7 95% C.I) though the difference was insignificant (p=0.135). Moreover, the prevalence of severe stunting was also high at 11.3% (8.6-14.6 95% C.I) with the prevalence being high in boys 12.3% (8.8-17.0 95% C.I) than in girls 10.2% (7.1-14.5 95% C.I) though the difference was insignificant (p=0.411).

Table 13: Prevalence of Stunting by Age Based on Height-for-Age Z-Scores

Age (mo)	N	Severe stunting (<-3 z-score)		Moderate stunting (>= -3 and <-2 z-score)		Normal (>= -2 z score)	
		n	%	n	%	n	%
6-11	121	9	7.4	17	14.0	95	78.5
12-23	240	21	8.8	69	28.8	150	62.5
24-35	169	23	13.6	42	24.9	104	61.5
36-47	163	20	12.3	38	23.3	105	64.4
48-59	150	22	14.7	30	20.0	98	65.3
Total	843	95	11.3	196	23.3	552	65.5

The above figure shows the stunting rates in Kajiado County by various age groups. The prevalence of severe stunting was highest in the age group 48-59 (14.7%) and lowest in the age group 6 – 11 (7.4%). In addition, the prevalence of stunting increased with age.

²⁰ Who guidelines for stunting: < 20% - Low, 20%-29% - Medium, 30%-39% - High and >40% - Alarming/Critical

2.4 Children's Morbidity

2.4.1 Morbidity Two Weeks Prior to Survey

A two-week child morbidity recall (inclusive of the day of the survey) was assessed to establish the prevalence of common illnesses among the children less than 5 years in Kajiado County. The results of the survey showed that 37.6% of the sampled children had been sick during the recall period.

Table 14: Proportion of Children Sick during the Two Weeks Recall Period

Proportion of children sick during the recall period	37.6% (348)	926
--	-------------	-----

Among the sick children, Acute Respiratory Infection (ARI) was the most prevalent infection during the period where 50.6% of the sampled children had suffered from the sickness; this was followed by fever at 21.0%, then the prevalence of diarrhea was 14.9% while other sicknesses contributed to 13.9%. Clearly, the analysis shows that there was a high rate of childhood diarrhea among the sampled children. This is shown in the figure below:

Figure 4: Morbidity

Although none of the children had suffered measles two prior to the survey, measles cases have been recorded especially in Kajiado North. One health facility (Eiiti) in Oldorko Sub-Location, Ngong Division reported 19 suspected cases between April and September, a period of six months. The cases of suspected measles from the DHIS for Kajiado County between January and September 2012 were 441 where 253 cases were from Kajiado North, 108 cases from Kajiado Central and the rest (80) from Loitokitok. However, a measles campaign was done in Kajiado North the week after the survey, 15th to 19th September where 59,811 children were vaccinated.

2.4.2 Health Seeking Behavior

District		Private Clinic	Shop/ Kiosk	Public Clinic	Mobile Clinic	NGO/ FBO	Local Herbs	No Assistance	TOTAL
Kajiado Central	N	11	18	56	1	2	1	13	102
	%	10.8	17.6	54.9	1.0	2.0	1.0	12.7	100
Kajiado North	N	22	13	53	0	2	2	14	106
	%	20.8	12.3	50.0	0	1.9	1.9	13.2	100
Loitokitok	N	30	16	39	2	3	2	13	105
	%	28.6	15.2	37.1	1.9	2.9	1.9	12.4	100
Total	N	63	47	148	3	7	5	40	313
	%	20.1	15.0	47.3	1.0	2.2	1.6	12.8	100

The health seeking behavior by the caregivers of the sick children was assessed by asking the respondents whose children had been sick in the 2 weeks recall period if they sought any medical interventions. The results showed that the health seeking behavior among the caregivers was commendably high at 87.2% for those who sought medical attention once their children were sick. Nevertheless, 12.8% of the caregivers did not seek any medical attention once their children were sick. Preference was given to the public clinic/hospital where 47.3% of the caregiver reported having sought health service. Further 20.1% of the caregivers sought medical attention from the private clinics while 15.0% of the caregivers had sought medical attention from the shops and clinics.

2.5 Vaccination Coverage

Figure 5: OPV, BCG and Measles Coverage

The results above show that the OPV 1, OPV 3 and BCG coverage were commendably high in the County above the national target of 80%. Overall, the OPV 1 coverage was 96.4% where 69.9% of this proportion was affirmed by the card and 26.5% was affirmed by recall. In addition, the coverage of BCG was 97.2% where 68.8% was confirmed by the card and the rest (28.4%) was confirmed by recall. The coverage of OPV 3 was estimated to be 92.5% where 66.6% was confirmed by card 25.9% by recall. On measles, it's only children who were nine months and above who are eligible for vaccination. The measles coverage was estimated to be 85.5% where 57.3% was confirmed by card and the rest (28.2%) was confirmed by recall. This shows that the coverage of measles was high above the national target of 80%. However, when compared with the last years' survey results there was a significant reduction of the OPV 1, OPV 3 and measles coverage's. This is demonstrated in the table below:

Table 15: Comparison of Vaccination Coverage for 2012 and 2011

	2012		2011		P-Value	Comments
	Proportion	N	Proportion	N		
OPV 1	96.4% (878)	911	98.7% (739)	749	0.002	Significant Reduction
BCG	97.2% (886)	911	No Data			Not comparable
OPV 3	92.5% (842)	911	96.8% (719)	743	0.000	Significant Reduction
Measles	85.5% (714)	836	90.1% (607)	674	0.006	Significant Reduction

Also worth noting is that although the county coverage immunization coverage is excellent, in some sub locations and village pockets, the coverage was significantly low. See annex for immunization analysis by clusters.

2.6 Vitamin A Supplementation and De-Worming

Vitamin A supplementation is among the High Impact Nutrition Intervention (HiNi). The supplementation starts at 6 months, and ideally should be repeated every 6 months until a child reaches the age of 5 years. Children between 6 and 11 months are supposed to be supplemented once while those aged between 12 and 59 months are supposed be supplemented twice in twelve months.

Figure 6: Vitamin A Supplementation

The overall prevalence of Vitamin A supplementation was 46.9% where the prevalence was highest (64%) among the children aged 6 – 11 months while among the children aged 12 to 59 months, the prevalence was 44.0%. In addition, among the children aged 12 – 59 months who are supposed to be supplemented twice in a year, majority (72%) of them were supplemented once and those who were supplemented twice were 24% and 4% had been supplemented thrice. The coverage of Vitamin A supplementation was significantly below the national target of 80%.

On de-worming which is given to children 12 to 59 months the survey established the prevalence as 34.9% using both the card and recall as shown in the figure below. This prevalence is way below the national target of 80%.

Figure 7: Prevalence of De-worming

The table below presents the comparison between Vitamin A Supplementation and De-worming for 2011 and 2012 surveys.

Table 16: Comparison of Vitamin A and De-worming for 2011 and 2012

	2012		2011		P-Value
	Proportion	N	Proportion	N	
De-worming	34.9% (263)	755	36.2% (225)	622	0.6162
Vitamin A Supplementation					
6 – 11 Months	64% (83)	130	No Data	No Data	No Data
12 – 59 Months	44% (332)	755	No Data	No Data	No Data
6 – 59 Months	46.9% (415)	885	60.8% (458)	753	0.0000

According to the above results, the prevalence of de-worming among the children had decreased from 36.2% to 34.9% though the decrease was insignificant ($p=0.6162$). On the other hand the overall prevalence of Vitamin A among the children had decreased significantly from 60.8% in 2011 to 46.9% in 2012 ($p=0.0000$).

2.7 Zinc Supplementation

Zinc supplementation has been shown to be effective for preventing diarrhea in children. When used as a therapy for acute or persistent diarrhea, zinc reduces the duration of the episode as well as its severity and complications. WHO/UNICEF²¹ recommends use of zinc for 10-14 days for all episodes of diarrhea among children under 5 years. Zinc supplementation paired with low osmolality ORS have been recognized as important approaches to tackle childhood diarrhea²². One of the HiNi intervention targets is to increase therapeutic zinc supplementation for diarrhea to 50%.

Figure 8: Management of Diarrhea

Among the children who suffered from diarrhea two weeks before the survey, 54.2% (n=28) were given ORS, 11.9% (n=6) were given home-made liquid. Only 1.7% (n=1) was supplemented with zinc. The zinc supplementation prevalence was therefore way below the target yet the zinc is available in most of the health facilities and staffs have been trained on enhanced management of diarrhoea. The low zinc coverage could be attributed to the health workers not telling the beneficiaries the use of supplements while the beneficiaries only know that ORS was essential in management of diarrhoea but assumed Zinc was just like any other drug.

2.8 Maternal Indicators

2.8.1 Maternal Physiological and Nutrition Status

Nutrition status of the women was determined for all mothers/caregiver in the child bearing age (15-49 years) whose children aged 0 – 59 months had been included in the anthropometric survey. Of the

²¹ WHO/UNICEF Joint Statement: Clinical Management of Acute Diarrhea, 2004

²² Best Practice Paper-Micronutrient Supplements for Child Survival (Vitamin A and Zinc) (2008)

caregivers included in the survey, 97.7% (n=638) were aged between 15 and 49 while the rest 2.1% (n=14) were aged over 49 years.

Table 17: Maternal Physiological Status

Status	Frequency	Percent
Currently breastfeeding (<6 months)	75	11.8
Currently breastfeeding (>6 months)	310	48.6
Pregnant and breastfeeding	2	0.3
Not pregnant/not breastfeeding	181	28.4
Pregnant	56	8.8
No Response	14	2.2
Total	638	100.0

The survey results showed that of the women aged 15 – 49 years, 48.6% (n=310) were currently breastfeeding with children being more than 6 months, 28.4% (n=181) were neither pregnant nor breastfeeding, 11.8% (n=75) were at the time of the survey breastfeeding with their children being less than 6 months old.

Figure 9: Maternal Nutrition

On maternal nutrition status, the study established that that 2.6% (n=17) were malnourished where there MUAC measurement was below 21 cm. Further, 10.9% (n=70) were at risk of malnutrition since their MUAC measurement was between 21 and 23. In addition, for the pregnant and lactating women, 3.1% of them were malnourished with 14.5% of the mothers being at risk of malnutrition. Based on the

above then the risk of malnutrition was low for the non-pregnant and lactating women than those who were pregnant and lactating through the difference was insignificant.

2.8.2 Micronutrient Supplementation

HiNi advocates for iron and vitamin A supplementation among the pregnant and lactating women respectively. Iron supplementation in pregnancy is important in controlling anemia and routine iron supplementation is the current cornerstone of efforts to reduce iron-deficiency anemia. In addition, maternal vitamin A supplementation within two weeks of birth is crucial and recommended by WHO as a mean of boosting the content in breast milk as well as promotes recovery following delivery. Since iron supplementation and vitamin A are recommendation from the WHO then the caregivers were asked whether they had received any form of iron supplementation during their last pregnancy while those that were breastfeeding were asked whether they had received vitamin A. The target for the two as per the HiNi project is 80% coverage. The figure below presents the coverage of vitamin A and iron supplementation among the caregivers:

Figure 10: Maternal Iron and Vitamin A Supplementation

The results of the survey showed that the iron supplementation among the mothers was 69.9% while the prevalence of vitamin A supplementation was 29.8%. Though the prevalence of iron supplementation was high at 69.9%, this prevalence was below the national target. In addition, the prevalence of vitamin A supplementation was way below the national target of 80%. The low coverage of vitamin A supplementation recorded in this survey would be attributed to the fact that as demonstrated most women deliver at home (Figure11) and only call for assistance in case of complications (as revealed by the key informants). In addition, as a cultural practice among the Maasai, after delivery, the new mothers' stays indoors for almost three months and they most of the times sends the child with a friend or relative for the first immunization. Others bring their children at 6 weeks when it is not safe to administer the Vitamin A supplement which is supposed to be administered within the first four weeks after birth. With a 77.9% reporting rate in DHIS (91.7% Loitoktok, 85.2% North

Kajiado & 55.3% Central) in last quarter April- June, 5663 <1 received Vit A, 5581 > 1yrs old, 2145 PLWs & 179 therapeutic VIT A .

A high proportion of women delivering at home was also reported in the county. According to the survey, 61.7% (n=399) of the caregiver delivered their last born child at home with no assistance from a skilled worker. In addition, 3.1% (n=20) of the caregiver delivered their last born child at home but with assistance of skilled attendants and the rest 27.8% (n=288) delivered at a health facility. This is shown in the figure below:

Figure 11: Place of Delivery

Reasons for the high proportion of home deliveries include: Poor health care access, with some health facilities being up to 70 km away in some of the sub locations. Poor infrastructure and lack of good communication networks worsens the health access. Highly patriarchal Maasai community in which the woman is not listened to & mothers in laws play the key role in determining child bearing and care practices. Due to the respect given to the older and, more experienced mothers, children born at home are still high. Culturally, labor is considered a natural process and therefore women are expected to be able to manage it without necessarily going to hospital. The cost of hospital delivery is also high (they have to buy delivery items in addition to 300ksh), compared to home deliveries where midwives charge 500/= or 700/= for delivering a female or male child respectively. Key informant interviews highlighted the fact that given the fact that Most PLWs are anemic due to poor dietary practices it is important that mothers are continually encourage to go for health facility deliveries. One of the partnering NGOs, Good Hands Organization, has been distributing complete delivery items together with an Antenatal package to 22 dispensaries in the county.

2.9 Infant and Young Children Feeding

Information of infant and young child feeding practices was obtained. In particular, much of the information was obtained based on a 24-hour recall, in line with the WHO guidelines to minimize recall bias and thus enhance more valid information.

Table 18: Infant and Young Children Feeding Practices

Indicator	2012		2011		P-Value
	Proportion	N	Proportion	N	
Continued Breastfeeding	77.7% (n=390)		No Data		
Timely Initiation to Breastfeeding (within the 1st one hour)	76.1% (186)	244	58.7% (175)	298	0.000
Exclusive Breastfeeding	44.7% (109)	244	14.7% (11)	75	0.000
Meal Frequency (6-8 months) - at least 2 meals (breastfed children)	89.6% (47)	49	No Data		
Meal Frequency (6-23 months) - at least 3 meals (breastfed only)	74.5% (200)	269	68.8% (121)	176	0.164
Meal Frequency (6-23 months) - at least 4 meals (non-breastfed only)	42.3% (22)	53	No Data		
2+ Meals for 6 - 8 months breast fed, 3+ 6 - 23 months breastfed and 4+ non breastfed	68.8% (222)	322	No Data		

Breastfeeding is very important for the young children since it strengthens the immunity of the young child among many other advantages. It is recommended that continuous breastfeeding should be continued up to 2 years. The results of the survey showed that among the children 6 – 23 months old, 77.7% (n=390) of them were still breastfeeding. Nevertheless, 46.4% (n=175) of the children 6 – 23 months were introduced to other foods apart from breast milk before they reached 6 months while 5.3% (n=20) were started on complementary feeding after 6 months.

The results of the survey showed that 76.1% (n=186) of the children age 0 – 5 months were initiated to breastfeeding within the 1st one hour. This was a significant improvement when compared with the previous survey result which was at 58.7% (n=158) (p=0.000). Exclusive breastfeeding practice up to 6 months is an important practice. WHO recommends that children 0 – 5 months be given nothing else besides breast milk. The results showed that the exclusive breastfeeding rate was 44.7% (n=109) which had significantly improved from 14.7%²³ (n=11) in 2011 (p=0.000). This was slightly higher than the national exclusive breastfeeding rate established by the Kenya Demographic Health Survey of 31.9%²⁴. Of the children who were not practicing exclusive breastfeeding, 18.9% were given plain water, 24.5% were given other liquids including sweetened water, glucose and porridge while the 50.2% were given cow milk and 6% of them were given fruit juice and fruits.

²³ Kajiado County SMART Survey, 2011

²⁴ Kenya National Bureau of Statistics, Kenya Demographic Health Survey, 2008-09

On the meal frequency, the proportion of children 6-8 months who fed at least twice and were breastfeeding was 89.6% (n=47) while the proportion of children 6 – 23 months who fed at least three meals for the breastfed children was 74.5% (n=200) though there was no significant change with the previous result of 2011 which was 68.8% (n=121) (p=0.164). For the children 6 – 23 months who had fed at least four meals and were not breastfeeding this proportion was 42.3% (n=22) while the proportion of those children 6 – 23 months who had fed two or more meals and either breastfed or non-breastfed was 68.8% (n=222).

Table 19: Food Groups among 6 - 23 Months

Food Type	n	Percent
Grains, Roots and Tuber	327	48.8
Legumes, Nuts, Seeds	154	23.0
Dairy Products	301	44.9
Flesh Products	39	5.8
Eggs	11	1.6
Vitamin A Rich Fruits and Vegetables	149	21.3
Other Fruits and Vegetables	102	15.2
Oils and Fats	300	44.8

The above table presents the eight food categories that the children 6 – 23 months old were fed the previous day preceding the survey. The caretaker was asked what the child had eaten/drank in the last 24 hours. According to the results, grains, roots and tuber were the most prevalent group of food that the children had eaten the previous day 48.4% (n=327); this was followed by dairy products (milk and milk products) where 44.9% (n=301) of the children had consumed dairy products.

The above food groups were coded as “1” if the child consumed and “0” if the child did not consume. To generate the dietary diversity score, all the eight food groups were summed and a single variable generated which ranged between 0 and 8. The higher the score meant that the child consumed from more food groups while the less the score then the child consumed from less food groups. The generated indicator was used to generate the required indicators for the various categories of children as indicated in the table below:

Table 20: Dietary Diversity

Indicator	2012		2011		P-Value
	Proportion	N	Proportion	N	
Consuming 3+ Food Groups (Breastfed Children)	75.8% (204)	269	No Data		
Consuming 4+ Food Groups (Non-Breastfed Children)	69.8% (37)	53	No Data		
Consuming 3+ or 4+ Food Groups (Breastfed and Non-Breastfed)	72.8% (234)	322	No Data		

The proportion of children 6-23 months old who were consuming three and more food groups among the breastfeeding children was 75.8% (n=204) while those who were feeding on four or more food groups and were not being breastfed was 69.8% (n=37). In addition, the proportion of children 6 – 23

months old who were consuming three or more food groups or four and above food groups for the breastfed and non-breastfed respectively was 72.8% (n=234). The result shows that the dietary diversity among the children aged 6 – 23 months was high since in all the three indicators for dietary diversity, they were more than 50%. Finally, the mean dietary diversity score among the children 6 – 23 months was 3.7 (S.D=1.4).

2.10 Household Food Security and Livelihood Source

2.10.1 Household Food Consumption and Dietary Diversity

Figure 12: Household Food Consumption

The above figure presents the percentages of meals which are usually eaten by the respondents per day and the percentage of meals eaten the day preceding the survey. According to the results of the survey, majority of the respondents (69.4%) usually eat 3 meals per day, this was almost the case when 69.1% of the respondents confirmed eating 3 meals the day preceding the survey. However, fewer people than usual ate over three meals the day preceding the survey (3.4% against usual 7.1%). In addition more people ate one meal and two meals that they usually eat. However, the difference was not significant between the number of meals usually eaten and what the respondents had eaten the previous day preceding the survey ($p > 0.05$). In addition, an analysis of difference between proportions shows that there was no significant difference between the proportion of households reporting having taken three meals the day preceding the survey (69.1%) and the normal/usual proportion (69.4%) of members taking three meals a day ($p > 0.05$). This may suggest that the prevailing household food security situation in the community was normal.

The 24-hours' food intake recall by the household members over 5 years old was used as a proxy to assess household dietary diversity in the community.

Figure 13: Food Dietary Diversity Score

According to the above figure, 60.4% (n=422) of the population over 5 years had consumed food between four and five food groups which is classified as medium. In addition, 28.1% (n=) had eaten from less than or equal to three food groups which is considered low and the rest 11.5% (n=80) had eaten from over six food groups which is considered high. Overall 70% of the population reported having consumed from at least four food groups which is commendable and recommended, leaving approximately 30% of the population sampled that had eaten from less than four food groups.

Table 21: Food Groups among Over 5 Years

Food Type	n	Percent
Grains, Roots and Tuber	657	98.1
Legumes, Nuts, Seeds	374	55.3
Daily Products	481	71.8
Flesh Products	133	19.9
Eggs	23	3.4
Vitamin A Rich Fruits and Vegetables	345	49.4
Other Fruits and Vegetables	180	26.9
Oils and Fats	583	87.0

The above table demonstrates that the most prevalence food group among the sampled population was grains, roots and tuber which had been consumed by 98.1% (n=657) of the sampled population. This was followed by those fats and oils which had been consumed by 87% (n=583) of the sampled population and the daily products had been consumed by 71.8% (n=481) of the sampled population. Of worry is the small proportion of the respondents who had consumed flesh products (meat, liver e.t.c.) and eggs which may be attributed to high prices of these products in the market for the non-pastoralist and for the Maasai community, traditionally, eggs, poultry and fish were traditionally not eaten. In

addition, Maasai diet has also evolved from meat and milk to include mainly “githeri²⁵”, maize meal and rice with potatoes and cabbages. The evolution may be attributed to the frequent droughts in the recent past which reduced their livestock significantly and with this being their main source of livelihood it is not then tenable to slaughter these animals now and then.

2.10.2 Food Aid

World Food Programme in partnership with Neighborhood Initiative Assistance (NIA) as the lead agency in Kajiado has been distributing General Food Distribution (GFD). Kajiado falls within the Agro-pastoralist zone and a new approach which factors in seasonality and a new calendar for distributing food aid for these areas has been adopted. The target areas are the rural areas of Kajiado County and the target population has been 86,720 individuals. The last distribution before the survey was conducted in August. The table below presents the food aid distribution in Kajiado County.

Table 22: Food Aid

		Proportion	N
	Received Food Aid	32.8%	656
Source of Food Aids	WFP/NIA	98.2%	216
	Child Fund	1.0%	
	Other	0.8%	
Frequency of Food Aid	One	59.2%	
	Two	24.6%	
	Over Three	16.2%	
Uses of Food Aid Received	Consumed by HH Members	80.4%	
	Shared with Kins	19.2%	
	Bartered for other Item	50.0%	
Duration Food Aid Lasted	< 1 Week	33.5%	
	1 Week	31.2%	
	2 Weeks	13.6%	
	3 Weeks	10.0%	
	4 Weeks or More	11.8%	

Among the surveyed households, 32.8% (n=216) had received food aid within the three months preceding the survey. In addition, among those who had received food aid, nearly all had received from the World Food Programme in conjunction with NIA, 1% had received from Children Fund while 0.8% had received food aid from other sources. Further, 59.2% of the households that had received food aid reported that they had received it once with the three months preceding the survey while 24.6% reported that they had received it twice. WFP/ NIA confirmed distributing food twice in the targeted period. The survey showed that 80.4% of those who had received food aid consumed it with the household hold members, 50% of them said that they had battered a portion of the food aid for other items while 19.2% reported that they had shared a portion with their kins. On the longevity of the food

²⁵ Mixture of Maize and Beans

aid, 33.5% reported that it lasted for less than one week, 31.2% reported that it had lasted for only one week while 13.6% reported that the food aid had lasted for 2 weeks and the rest (21.8%) for more than 3 weeks. Among the items mentioned by the respondents as having been received during the food aid were CSB, Oil, Pulses, Maize/Maize Meal, wheat meal, rice among others. The actual ration per person is displayed in the figure below:

Table 23: Actual Ration per Person in Kajiado

Ration	Quantity per Person
Cereals	6Kgs
Pulses	1.2Kg
Vegetable Oil	o.4L
CSB	0.6Kg

2.10.3 Livelihood Sources

Table 24: Livelihood Sources

		Percent
Occupation of HH Head	Pastoralist	37.6%
	Farmer	11.6%
	Local Merchant/Petty Trade	15.5%
	Daily Laborer/Wages	12.9%
	Jobless	1.0%
	Military	0.4%
	Employed	8.9%
	Charcoal Burning	1.0%
	Sand Harvesting	0.7%
	Others	6.2%
Main Source of Livelihood	Livestock	38.3%
	Farming	12.2%
	Agriculture-Pastoral	1.4%
	Trader	3.6%
	Salaried Employment	9.7%
	Petty Trade	10.9%
	Charcoal Burning	0.7%
	Casual Work	14.4%
	Others	4.7%
Main Source of Food Consumed	Own Production	11.9%
	Purchases	83.7%
	Gifts from Friends/Family	0.3%
	Food Aids	0.1%

The results in the above table show that the main occupation of the household head was pastoralist at 37.6%, this was followed by the local merchant/petty traders at 15.5% and daily laborers accounted to 12.9% of the sampled population. In addition, the main source of livelihood in Kajiado County was livestock at 38.3% followed by casual work at 14.4% and then agriculture at 12.2%. Finally, the main

source of food consumed was from purchases which was mentioned by 83.7% of the sampled households, this was followed by own production at 11.9%.

2.11 Water, Sanitation and ITNs

2.11.1 Water

The results of the survey showed that 35.9% (n=251) of the households had access to safe drinking while 64.1% (n=448) had no access to safe drinking water²⁶. Among the sources of water mentioned by the responded were water taps (33.5%), tanker (2.2%), unprotected wells (41.5%) while the rest were getting their water from lags and earthen dams. Of the 64% of the households that does not have access to safe drinking water, 27.1% of them treat their water before drinking while 74.7% do not treat the water. The most common method of treating water among the households that practice water treatment was boiling (67.4%), followed by use of chemicals (31.5%) and finally solar disinfection (1.0%). On average the households sampled consumed 58 liters per day with the average water used per person per day in Kajiado being 11 Litres. This is less than the minimum required as per sphere standards recommendation of 15 L per person per day²⁷. On the water storage, 89.7% (n=599) of the households sampled use Jerricans, 5.1% (n=34) use Tank while 3.4% (n=23) use buckets. This is shown in the table below:

Figure 14: Water

²⁶ Unsafe water means water from unprotected wells, laga and earthen dam/pans

²⁷ Sphere Handbook. **The Sphere Project**- Humanitarian Charter and Minimum Standards in Disaster Response

The above finding shows that a high percentage of the sampled households in Kajiado County do not have access to safe drinking water. In addition, among the households which do not have access to safe drinking water as recommended do not treat the water since the results demonstrates that there is minimal treatment of water at the household level among the sampled households. The role of untreated water as the main cause of childhood diarrhea cannot be underestimated. Nevertheless, it is encouraging from the results to find out that the most prevalence method of water treatment is boiling.

2.11.2 Sanitation

According to the survey, 45.4% (n=297) of the households sampled had access to either a toilet or a latrine facility while the rest 54.6% (357). The high proportion of households with no toilets would probably be attributed to migratory and socio-cultural lifestyles of the predominantly pastoralist communities resident in these areas.

On the type of the toilet which were available among the sampled households were; pit latrine (57.4% - n=163), traditional pit latrine (21.1% - n=60), ventilated improved pit latrine (20.4% - n=58), bucket (0.7% - n=2) and flush toilet (0.4% - n=1). In addition to the availability of toilets, the respondents were asked whether the toilets were in use where 99.3% (n=279) reported that the toilets were in use while only 0.7% (n=2) who reported that their toilets were not in use. In addition, among the households who reported that they did not have toilets, 95.8% (n=339) said they used a bush as a toilet while the rest 4.2% said that they used an open field as a toilet. On the disposal of the children faeces, 54.9% (364) of the households sampled reported that they disposed of the faeces immediately in the nearby bush or farm, 42.1% (279) reported that they disposed of the faeces immediately and hygienically. Hand washing at critical times²⁸ was found to be 23.6% (n=138). The use of open bush/field for faecal disposal coupled with consumption of water from open sources combined with poor hand washing at critical times poses a risk of contamination of drinking water, a pre-disposing factor to diarrheal diseases.

2.11.3 Insecticide Treated Mosquito Nets (ITNs)

Treated mosquito nets are provided free of charge to pregnant mothers attending the Ante-Natal Clinics (ANCs). According to the survey, 52.8% (n=354) of the sampled households reported having mosquito nets. The result above indicate that almost 1 out every 2 households do not have a mosquito net and therefore it is paramount for the Ministry of Health with other partners to devise mechanisms of distributing the ITN to the households in the community. Out of the households that had mosquito nets, 89.9% of them reported having obtained it from the Ministry of Health, 6.3% reported that they bought it from a shop while 0.6% said that they received the mosquito net form an agency. In addition, among the households which reported having mosquito nets, 54.3% said that they had only one, 33.2% reported that they had two nets while 12.5% reported that they had more than three nets. On the treatment of the mosquito nets, 41.5% of the nets had been treated while 9.5% had not been treated. It should be understood that all the MoH nets are treated and hence the 11.3% of the nets which were not treated were from other sources as indicated above. Among the nets which were from other source, only 9.5% were treated while 1.8% was not treated. For those nets which were treated from the

²⁸ Hand Washing at critical times includes washing hands after visiting toilet, before handling food, after cleaning Childs bottom, before feeding the child and before eating

household level, 47.8% had been treated more than 6 months ago while the rest (52.2%) had been treated less than 6 months ago. On the usage of the mosquito nets, slightly above 50% of the users were children less than 5 years while the other users included children older than 5 years (20%), and parents (15%). Nevertheless, it is worth noting that the results showed that approximately 5% of the households which had mosquito nets, these nets were not used by anybody in the household. This information is displayed on the table below:

Table 25: Insecticide Treated Mosquito Nets (ITNs)

		Proportion	N
	Availability of Mosquito Nets	52.8%	670
Source of Mosquito Nets	Shop	6.3%	354
	Agency	0.6%	
	MoH	89.9%	
	Other	3.2%	
Mosquito Nets Currently in Use	One	54.3%	354
	Two	33.2%	
	Three and More	12.5%	
Treatment of Mosquito Net	Yes	9.5%	354
	Already Treated	41.5%	
Time Last Treated Net	Less than a Month Ago	26.1%	33
	Between 1 and 6 Months Ago	26.1%	
	More than 6 Months Ago	47.8%	

3.0 Conclusion

In conclusion the prevalence of acute malnutrition of children in Kajiado County has improved. Overall the food and nutrition security situation has improved compared to last year as result of good long rains performance and improved water availability leading to good animal body conditions. The availability of milk, which is the staple food, at household level is however low, owing to low household stocks of livestock stemming from the trailing effects of the 2009 and subsequent droughts. Aggravating factors that are likely to alter the current nutrition and food security situation include poor rains in the Southern region, suggesting an inevitable shortfall of harvest, while in some locations, total crop failure was experienced.

Although the prevalence of wasting is low and at acceptable levels, concern is on the high prevalence of stunting levels, hence high chronic malnutrition. “Stunting in children below the age of five is a stronger indicator of hunger and one of its determinants, poverty, than other anthropometric indicators or estimates of per capita income. This is because stunting indicates the chronic restriction of a child’s potential growth, reflecting the cumulative effects of inadequate food intake and poor health conditions that result from endemic poverty’ (United Nations Standing Committee 2010)²⁹.

In order to successfully and sustainably address stunting, it is critical that an integrated approach is applied. While stand-alone nutrition interventions are important, it is equally important to ensure a multi-sectoral approach that tackles, among others, women’s empowerment, maternal education, the promotion of exclusive breastfeeding for the first six months, decreasing infections, the disease burden, improved access to healthcare, improved sanitation, and increased agricultural production& other livelihood programs.

HINI components are still low especially Vitamin A coverage (and in particular among the 12- 59 months who took the supplements twice in the last 1 year); Zinc supplementation in managing diarrhoea is low. De-worming coverage is also low as well as exclusive breastfeeding rates. Although the overall county immunization coverage for measles, OPV and BCG are excellent, some pockets of concern have very poor coverage, especially in Kajiado North. There is still stigmatization of HIV/AIDS: It is taboo to discuss the subject openly.

²⁹ Jane Badham, Lara Sweet. 2010; Stunting: An Overview. SIGHT AND LIFE Magazine

4.0 Recommendations

Short term/ mid term

- Frequent measles vaccination campaigns especially in areas where access to health facilities is a main challenge, with timely interventions when suspected cases are highlighted.
- Mothers of infants and young children require much health and nutrition education, as the available research shows that effects on linear growth seem to be best with interventions that also provide specific educational messages such as importance diet diversity and emphasize of the critical window of opportunity that exists for optimal nutrition from preconception to two years.
- Scaling up HINI indicators is essentially (especially Vitamin A supplementation, de-worming and using Zinc for diarrhoea management) as well as iron supplementation for PLWs through strengthening of outreach services to supplement long distance/ access to health facilities.
- Roll out of micronutrient supplementation program in districts that have not yet started (e.g. central) with refresher training for health facility staffs especially in Kajiado central on enhanced management of diarrhoea in order to promote Zinc usage.
- District based surveillance systems could be established to help individual districts monitor the HINI indicators at relatively lower costs.
- Implementation of the community strategy which also addresses challenges of access to the health facilities should be supported by MoH and its partners in the various districts.
- Specific pocket areas where the GAM/ SAM might be of concern e.g. flower farms, slums etc can be addressed by continuous surveillance and if need be appropriate targeted interventions done in those areas.
- Streamline and adherence to the admission criteria to targeted nutrition program among all partners working in IMAM.
- Partners should invest in more Livelihood intervention programs and scale up interventions such as adopting livelihood diversifications to have a shift from over-dependence on pastoralist & adopt income generating activities e.g. small scale trade, more market participation e.g. selling livestock products, bee keeping & honey production.
- It is necessary to have health education sessions on HIV targeting all community members (both infected and non infected/ affected at the community level to help reduce stigma and also to address information gap on IYCN in the context of HIV.
- DHMT Central and the district hospital should look into the concerns raised about the district hospital and work at restoring community confidence on service delivery.

Long term

4. MoH & Partners need to invest in address the Health care access challenges (distance, attitude) by constructing more health facilities and the need to continually encourage hospital deliveries.
5. Cultural reasons for home deliveries should be addressed through continuous health education while exercising best practices in behaviour change communication.
6. Scale up WASH program to cover all areas of the county in both urban, semi urban and the rural areas
